

Abstract

The invention relates to a disposable diaper (2), in particular for incontinence use, with a hip belt (4), forming a waist opening of the diaper, sealed in the peripheral direction, which may be opened and closed in at least one position and which has a main diaper section (6) with a front region (8), a back region (12) and an intermediate a crotch region (10), comprising an impermeable layer (14) (back sheet), facing away from the body and a permeable layer (top sheet), facing the body, and with an absorption body for bodily fluids. The main diaper section (6) may be detachably fixed to the hip belt (4), by means of first closing elements (20) at the longitudinal end (18) of the front region (8) or the back region (12), such that a user can bring the main diaper section (6) through the legs, with a hip belt fitted, and detachably fit the still free longitudinal end of the main diaper section (6) to the hip belt (4). According to the invention, the applicability of such a diaper may be extended, wherein said diaper is embodied with second closing elements (26), in addition to the first closing means (20), acting between the hip belt (4) and the longitudinal ends (18) of the main diaper section (6), which can form a fitting connection between the hip belt (4) at one end and the front region (8) or crotch region (10) of the main diaper section (6) at the other end and which can be arranged such that, after detaching the first closing means (20), the front region (8) of the main diaper section (6) can be turned or folded away from the hip belt (4).
